Objective:

- Implementing and analyzing an application of Queue.

TASK 1: DECK

A Double Ended Queue (**Deque (also called as DECK)**) is a queue in which you can insert and remove elements both at the *front* and at the *rear end* of the queue. You task is to create a class **Deque**, with the following interface:

- void insertAtTail (T).
- void insertAtHead(T).
- T deleteAtTail( ).
- T deleteAtHead( ).
- isEmpty():
- isFull():
- int getCapacity()
- int getNoOfElements()

Write routines to support the deque that take O(1) time per operation.

TASK 2: HOT POTATO

One of the typical applications for showing a queue in action is to simulate a real situation that requires data to be managed in a FIFO manner. To begin, let's consider the children's game Hot Potato. In this game (see Figure http://interactivepython.org/courselib/static/pythonds/BasicDS/queues.html - fig-quhotpotato) children line up in a circle and pass an item from neighbor to neighbor as fast as they can. At a certain point in the game, the action is stopped and the child who has the item (the potato) is removed from the circle. Play continues until only one child is left.

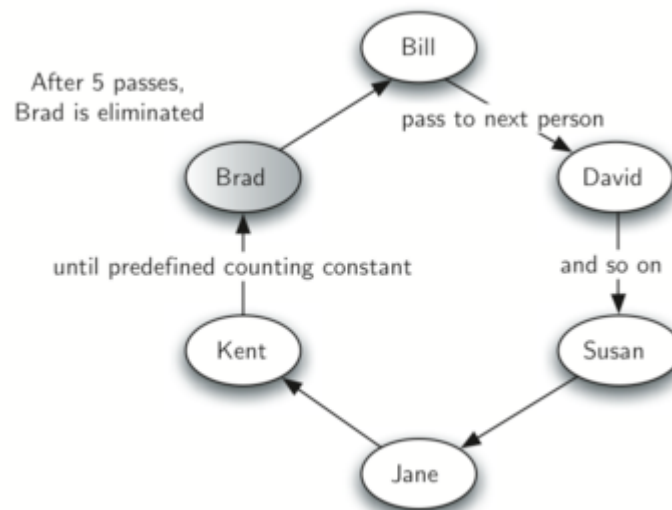

Figure 1: A Six Person Game of Hot Potato

This game is a modern-day equivalent of the famous Josephus problem. Based on a legend about the famous first-century historian Flavius Josephus, the story is told that in the Jewish revolt against Rome, Josephus and 39 of his comrades held out against the Romans in a cave. With defeat imminent, they decided that they would rather die than be slaves to the Romans. They arranged themselves in a circle. One man was designated as number one, and proceeding clockwise they killed every seventh man. Josephus, according to the legend, was among other things an accomplished mathematician. He

instantly figured out where he ought to sit in order to be the last to go. When the time came, instead of killing himself, he joined the Roman side. You can find many different versions of this story. Some count every third man and some allow the last man to escape on a horse. In any case, the idea is the same.

We will implement a general simulation of Hot Potato. Our program will input a list of names and a constant, call it "**num"** to be used for counting. It will return the name of the last person remaining after repetitive counting by num. What happens at that point is up to you.

To simulate the circle, we will use a queue (see Figure 2). Assume that the child holding the potato will be at the front of the queue. Upon passing the potato, the simulation will simply **dequeue** and then immediately **enqueue** that child, putting her at the end of the line. She will then wait until all the others have been at the front before it will be her turn again. After num **dequeue**/**enqueue** operations, the child at the front will be removed permanently and another cycle will begin. This process will continue until only one name remains (the size of the queue is 1).
